Understanding Photonic Crystals and Their Modeling Challenges

What Are Photonic Crystals?

Photonic crystals are materials with periodic variations in dielectric constant (permittivity), typically structured at scales comparable to the wavelength of light. These periodic variations create photonic band gaps—frequency ranges where electromagnetic waves cannot propagate through the crystal—analogue to electronic band gaps in semiconductors. This property enables precise control over light behavior, making photonic crystals invaluable for applications like waveguides, filters, and resonators.

Why Simulate Photonic Crystals?

Simulating photonic crystals allows researchers to:

- Design structures with desired optical properties, such as specific band gaps or defect modes.
- Predict electromagnetic field distributions within complex geometries.
- Optimize parameters like lattice constants, filling fractions, and defect configurations.
- Reduce experimental costs by pre-validating models computationally.

Challenges in Modeling Photonic Crystals

Modeling photonic crystals involves solving Maxwell's equations in complex, periodic media, which presents several challenges:

- High computational demands for 3D simulations.
- Accurate representation of complex geometries, especially for defect structures.
- Handling large matrices resulting from discretization.
- Ensuring convergence and stability of numerical methods.

To address these issues, several numerical techniques are employed, with the Plane Wave Expansion (PWE) method being among the most popular for initial band structure calculations.

Key Techniques for Photonic Crystal Simulation in MATLAB

Plane Wave Expansion (PWE) Method

The PWE method is based on expressing the periodic dielectric function and electromagnetic fields as Fourier series. This approach transforms Maxwell's equations into an eigenvalue problem, which MATLAB can efficiently handle. Its main advantages include:

- Straightforward implementation for periodic structures.
- Good accuracy for calculating band diagrams.
- Flexibility in handling 2D structures (e.g., photonic crystal slabs).

However, PWE is less suited for complex defects or non-periodic structures, where finite-difference or finite-element methods might be preferable.

Finite-Difference Time-Domain (FDTD) Method

While not the focus here, FDTD is another powerful technique, especially for modeling defects and finite structures, but it generally requires more computational resources and complex coding.

Choosing the Right Approach

For many initial studies and educational purposes, PWE-based MATLAB codes strike an excellent balance between simplicity and accuracy, making them ideal for understanding fundamental photonic crystal behaviors.

Structure of a Typical Photonic Crystal MATLAB Code

Creating a MATLAB code for photonic crystal simulations involves several key components. Here, we explore each in depth.

1. Defining the Lattice Geometry

The foundation of any photonic crystal simulation is its geometry. The code begins with specifying:

- Lattice type (square, hexagonal, triangular, etc.)
- Lattice constants (periodicity)
- Unit cell parameters

Example:

```
``matlab

a = 1; % lattice constant

theta = pi/3; % for hexagonal lattice

% Generate reciprocal lattice vectors accordingly

``
```

This sets the stage for defining the periodic dielectric structure.

2. Constructing the Dielectric Profile

The dielectric function $\epsilon(\mathbf{r})$ captures the material's optical properties. In PWE, it is expanded as a Fourier series:

$$\epsilon(\mathbf{r}) = \sum_{\mathbf{G}} \epsilon_{\mathbf{G}} e^{i \mathbf{G} \cdot \mathbf{r}}$$

$\mathbf{G}$

where $\mathbf{G}$ are reciprocal lattice vectors.

Implementation details:

- Define a grid of Fourier components $\mathbf{G}$.
- Assign dielectric constants to each Fourier component based on the geometry (e.g., high dielectric rods in air).

Example MATLAB snippet:

```

``matlab

% Generate reciprocal lattice vectors

Gx = ...; Gy = ...;

% Initialize Fourier coefficients

epsilon_G = zeros(Nx, Ny);

for m = -M:M

    for n = -N:N

        G_vector = m b1 + n b2; % b1, b2 are reciprocal lattice vectors

        epsilon_G(m+M+1, n+N+1) = computeEpsilonCoefficient(G_vector);

    end

end

``

```

This step is crucial for accurately representing the dielectric distribution.

3. Setting Up the Eigenvalue Problem

Maxwell's equations reduce to a matrix eigenvalue problem in the PWE approach:

$$\sum_{\mathbf{G}} \left(\mathbf{k} + \mathbf{G} \right) \left(\mathbf{k} + \mathbf{G}' \right) \mathbf{E}_{\mathbf{G}} = \left(\frac{\omega}{c} \right)^2 \epsilon_{\mathbf{G} - \mathbf{G}'} \mathbf{E}_{\mathbf{G}}$$

where:

- $\mathbf{k}$ is the wavevector in the Brillouin zone.
- ω is the angular frequency.
- c is the speed of light.
- $\mathbf{E}_{\mathbf{G}}$ are the Fourier coefficients of the electric field.

Implementation:

- Construct the matrix $A(\mathbf{k})$ based on the above relation.
- Use MATLAB's `eig` function to compute eigenvalues (frequencies).

Example:

```
```matlab
```

```
% Build the eigenvalue matrix
```

```
A = zeros(size(epsilon_G));
```

```
for i = 1:N
```

```
for j = 1:N
```

```
 G_i = G_vectors(:,i);
```

```
 G_j = G_vectors(:,j);
```

```
 A(i,j) = norm(k + G_i)^2 delta(i,j) - (omega/c)^2 epsilon_G(i,j);
```

```

end

end

% Solve for eigenvalues

[fields, omega_squared] = eig(A);

omega = sqrt(diag(omega_squared));

...

```

This eigenvalue problem is solved across various  $\mathbf{k}$ -points to produce the band diagram.

## 4. Calculating Band Structures

By sampling the wavevector  $\mathbf{k}$  along high-symmetry paths in the Brillouin zone (e.g.,  $\Gamma$  to  $X$ ,  $\Gamma$  to  $M$ ), the code computes eigenfrequencies at each point, producing the photonic band diagram.

Implementation:

```

```matlab

k_path = defineHighSymmetryPath();

for idx = 1:length(k_path)

    k = k_path(:,idx);

    A = buildEigenMatrix(k, epsilon_G);

    [~, eigvals] = eig(A);

    band_structure(:, idx) = sqrt(diag(eigvals));

end

...

```

Plotting these results reveals the photonic band gaps and guides design choices.

Optimizing MATLAB Code for Photonic Crystal Analysis

- Vectorize operations: MATLAB excels at matrix operations; avoid loops where possible.
- Use sparse matrices: Large eigenvalue problems benefit from sparse representations.

Physical Models for Dynamic Simulation

Carrier Rate Equations

At the core of dynamic modeling are the carrier rate equations, which describe the temporal evolution of carrier density $N(z,t)$:

$$\frac{\partial N(z,t)}{\partial t} = \frac{J(z,t)}{qV} - \frac{N(z,t)}{\tau_N} - G(N,z,t) \cdot S(z,t)$$

where:

- $J(z,t)$: injection current density
- q : electronic charge
- V : active volume
- τ_N : carrier lifetime
- $G(N,z,t)$: gain coefficient dependent on carrier density
- $S(z,t)$: photon density

This differential equation captures the generation, recombination, and stimulated emission processes, forming the basis for dynamic behavior analysis.

Optical Propagation Equations

The evolution of the optical field $E(z,t)$ or photon density $S(z,t)$ along the propagation axis is modeled via the coupled wave equations, often simplified to the traveling-wave equations:

$$\frac{\partial S(z,t)}{\partial z} + \frac{1}{v_g} \frac{\partial S(z,t)}{\partial t} = \Gamma \cdot G(N,z,t)$$

$$\frac{d}{dt} S(z,t) - \alpha S(z,t)$$

]

where:

- v_g : group velocity
- Γ : optical confinement factor
- α : internal losses

These equations are coupled with the carrier rate equations and require numerical methods for solutions.

Nonlinear and Additional Effects

In high-speed and high-power regimes, additional effects must be considered:

- Spectral dependence of gain and refractive index
- Four-wave mixing (FWM)
- Self-phase modulation (SPM)
- Cross-phase modulation (XPM)
- Two-photon absorption (TPA) and free-carrier absorption (FCA)
