```
``verilog
```

```
always @(posedge clk or posedge reset) begin
```

```
if (reset) begin
```

```
state
```

```
end else begin
```

```
case (state)
```

```
IDLE: if (start) state
```

```
SETUP: state
TRANSFER: if (transfer_complete) state
COMPLETE: state
ERROR: state
default: state
endcase
```

```
end
```

```
end
```

```
...
```

Step 3: Address Generation Logic

Implement counters and registers to generate source and destination addresses based on transfer parameters.

Step 4: Data Path Implementation

Design data registers, FIFOs, or buffers to facilitate data movement, ensuring synchronization with bus protocols.

Step 5: Bus Interface Integration

} state_t;

reg [2:0] state;

// Address counters
```

```
reg [31:0] current_src_addr;

reg [31:0] current_dest_addr;

reg [15:0] remaining_words;

// Control logic

always @(posedge clk or posedge reset) begin

if (reset) begin

state
done
error
end else begin

case (state)

IDLE: begin

if (start) begin

current_src_addr
current_dest_addr
remaining_words
state
end

end

SETUP: begin

// Initialize transfer parameters

state
end

TRANSFER: begin

// Implement data transfer logic here
```

```
if (remaining_words == 0) begin
```

```
    state
```

```
end else begin
```

```
    // Transfer one data word
```

```
    // Update addresses
```

```
    current_src_addr
```

```
    current_dest_addr
```

```
    remaining_words
```

```
end
```

```
end
```

```
COMPLETE: begin
```

```
done
```

```
state
```

```
end
```

```
ERROR_STATE: begin
```

```
error
```

```
state
```

```
end
```

```

```

```
endcase
```

```
end
```

```
end
```

```
endmodule
```

```
```
```

This polarization process enables selecting the most reliable channels for data transmission, effectively optimizing the code's performance.

Constructing Polar Codes

Constructing a polar code involves:

- Selecting code parameters:
 - Block length $(N = 2^n)$, where (n) is a positive integer.
 - Code rate $(R = K/N)$, with (K) being the number of information bits.
- Determining frozen bits:
 - Based on channel reliability metrics (e.g., Bhattacharyya parameters or mutual information).
 - Positions of frozen bits are fixed to known values (often zeros).
- Generator matrix:
 - Derived from the Kronecker product of the basic matrix $(F = \begin{bmatrix} 1 & 0 \\ 1 & 1 \end{bmatrix})$, raised to the power (n) .
- Encoding process:
 - Combining information and frozen bits into a vector.
 - Applying the generator matrix to produce the codeword.

In MATLAB, the construction process can be implemented using functions that generate the generator matrix and select suitable frozen bits based on channel conditions.
